

How to deal with electrical corrosion of optical cables

Overview

Once the electrical contacts are clean and dry, applying a protective compound inhibits future corrosion and moisture ingress. It is expected to stand up to direct burial in rocky terrain, the tenacious jaws of aggressive rodents, and to be able to withstand lightning strikes as well. When dirt, oil, moisture, or oxidation builds up on the metal. The anti-tracking AT outer sheath is widely used in practice, using non-polar polymer material as the base material, and the tracking-resistant PE outer sheath material also has good performance, and should be reasonably selected according to actual needs. These materials use inorganic fillers. There are two general types of corrosion that are of concern in electrical connections: oxidation and galvanic. Oxidation can develop on the connector as well as the conductor. Electrical corrosion in ADSS (All-Dielectric Self-Supporting) optical cables is a serious issue that can lead to the degradation and failure of the cable over time. It covers structural elements, international compliance standards, and performance expectations all formulated for system integrators, engineers, and project decision-makers.
